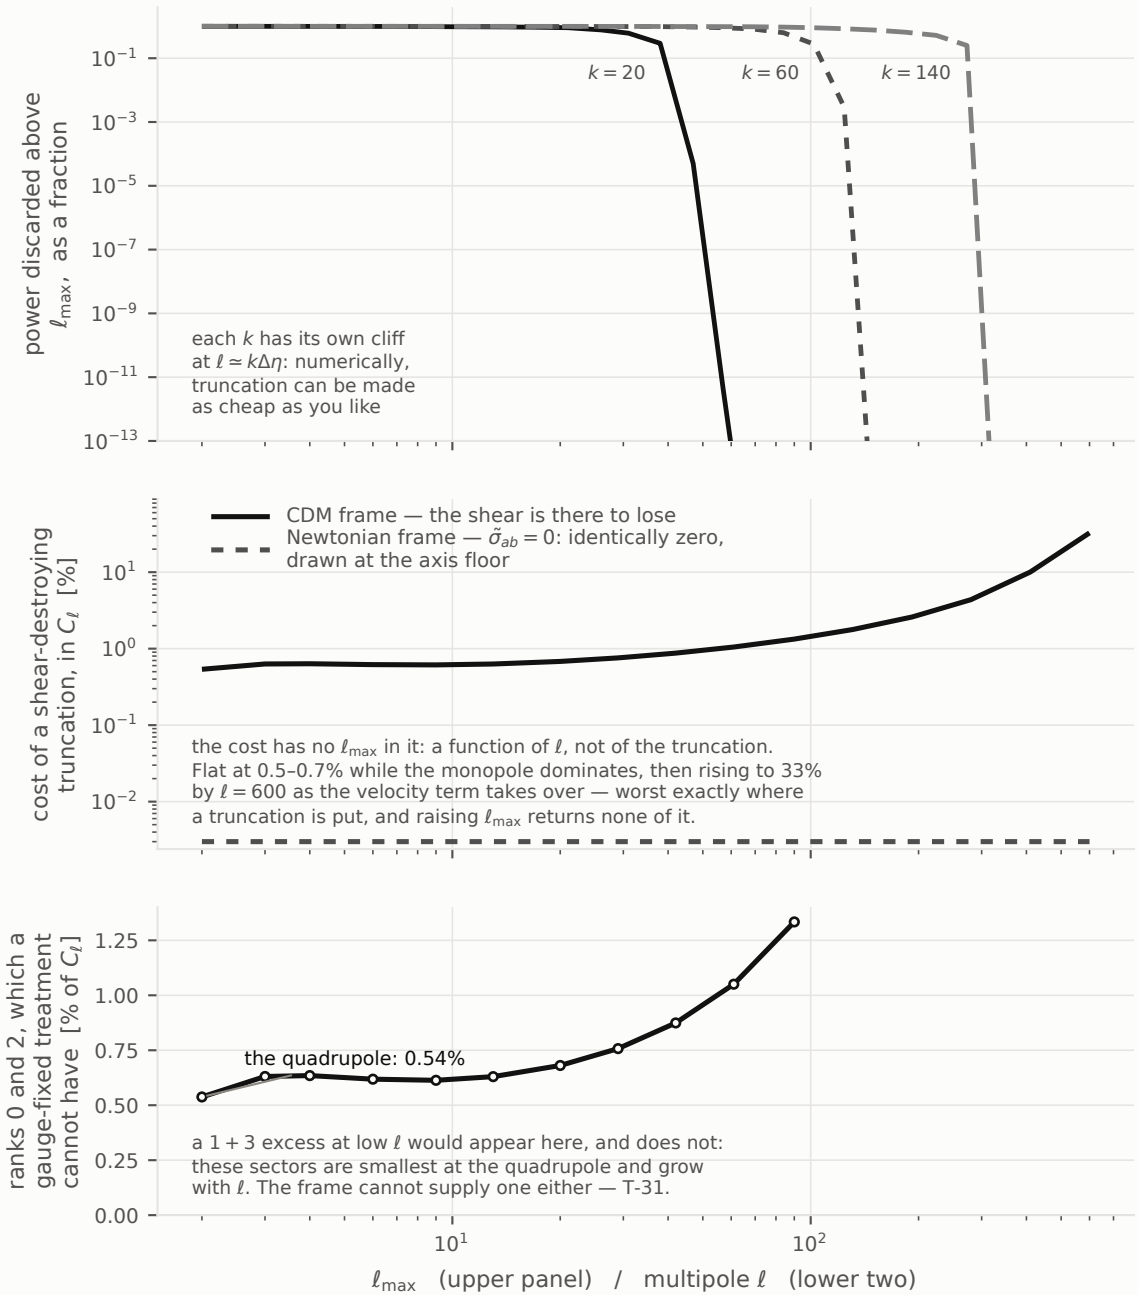
F2 Truncation: what it discards, and what it destroys


Appendix E: four consecutive vanishing harmonics force $\sigma_{ab} = 0$ exactly, and the paper rejects the argument that this is second order and so droppable — there are no first-order terms in that equation to drop it against. The upper two panels are the two quantities, and they do not shrink together: the first falls off a cliff, the second rises. Footnote 29 (p. 365) says the Newtonian frame removes the problem. It does, by having no shear to lose. The third asks whether the covariant sectors supply an excess at low ℓ: they do not.
