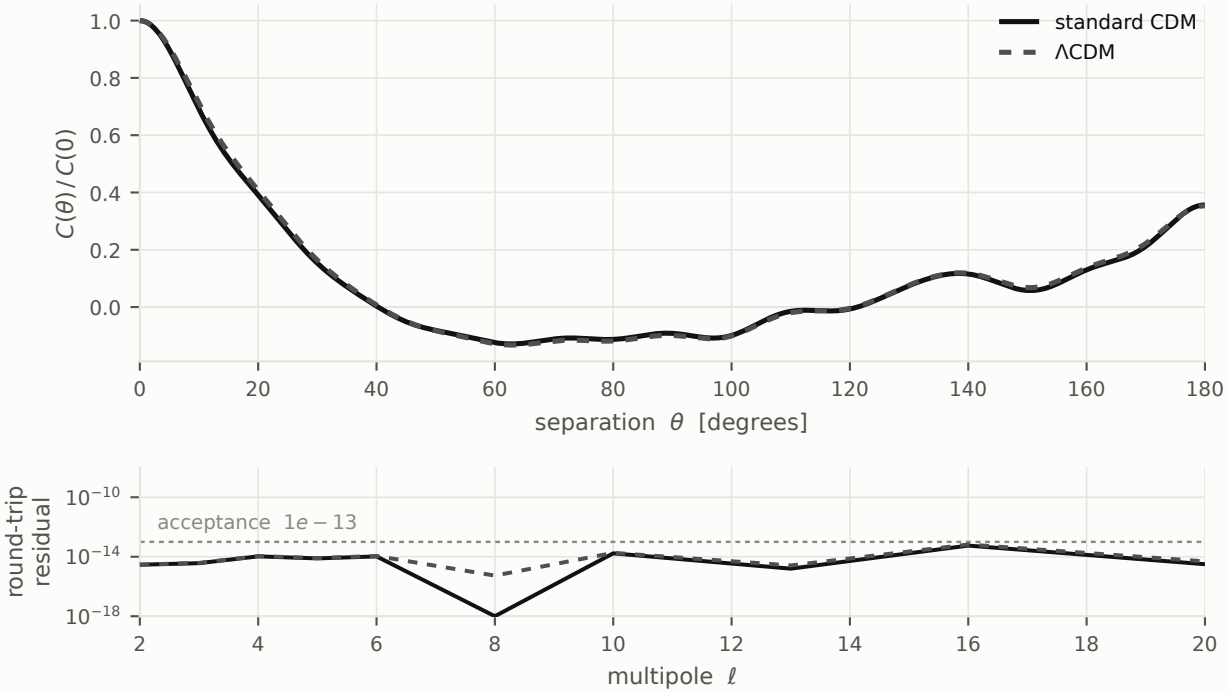
F4 The angular correlation function, and the transform that makes it

$C(\theta) = \sum_{\ell} \frac{2\ell+1}{4\pi} C_\ell P_\ell(\cos\theta)$, summed over $2 \le \ell \le 20$ — the range F3 claims. The lower panel is the Legendre round trip, which tests the transform and not the spectrum: the two share their C_ℓ.



Normalised to $C(0)$, so the comparison is of shape. Summing past $\ell = 20$ would draw multipoles this release does not stand behind, and a real-space curve hides which ℓ contributed — so the restriction is made here, not in a caption.
