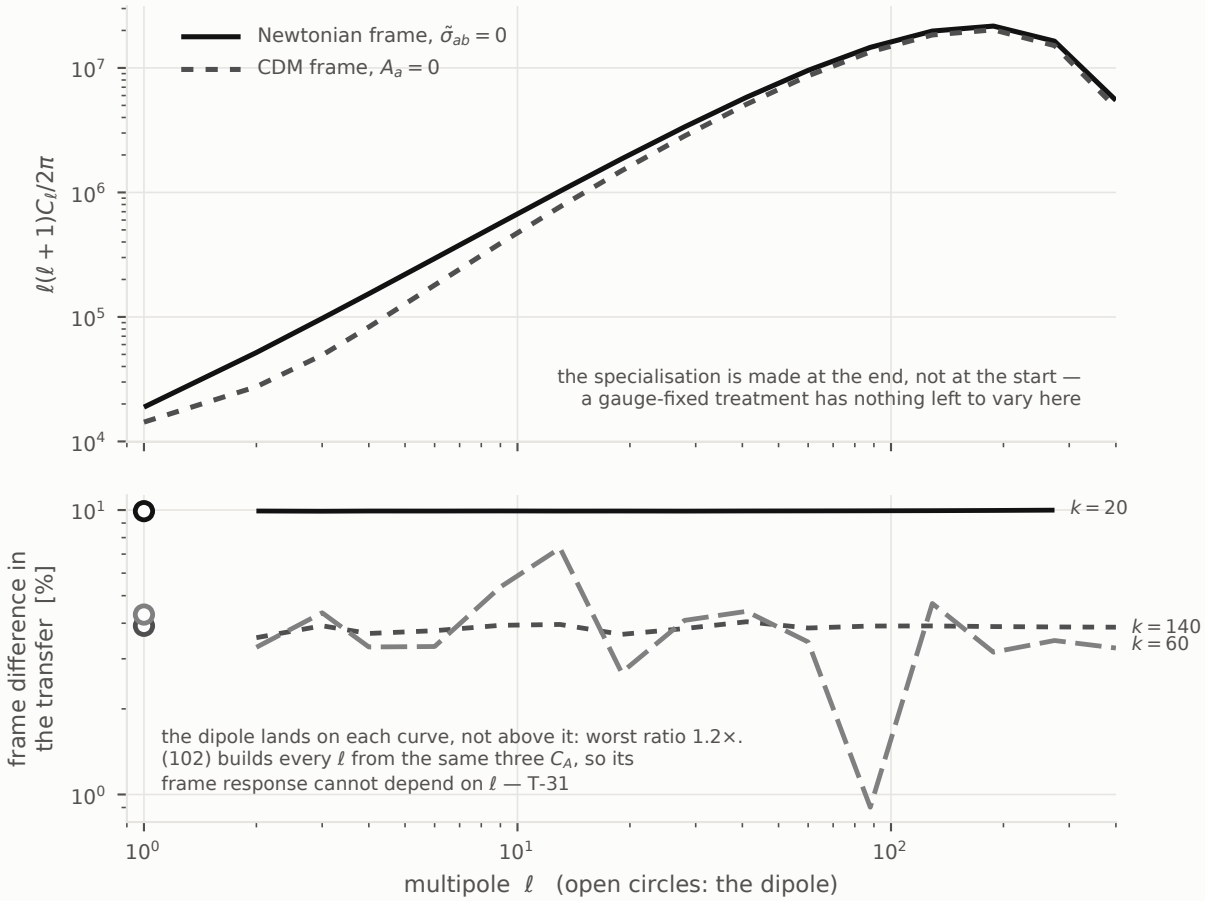
F7 Frame specialisation, and what (102) can say about it


The generic u^a is carried through and the frame chosen at the end: the Newtonian frame reproduces §7.1.1, the CDM frame extends it. The lower panel was planned to show the dipole standing apart — $\tilde{\tau}_a = \tau_a - v_a$ moves it and leaves $\ell \geq 2$ invariant. It does not, and the reason is structural, not numerical: finding T-31. A figure that reports this is more use than one that illustrates what was assumed.
